TITLE: On a theory of the nonlinear polarizability of crystals

SOURCE: Obninsk. Fiziko-energeticheskiy institut. Doklady, FEI-25, 1965. K teorii nelineynoy polaryzuyemosti kristallov, 2-15

TOPIC TAGS: tensor, crystal, electromagnetic radiation, Hamiltonian, Green function, Maxwell equation, Fourier series, exciton, phonon interaction, coulomb interaction, nonlinear effect, particle interaction, charged particle

ABSTRACT: The tensor of nonlinear polarizability of crystals ϵ_{ijl} for the exciton

region of the spectrum is found by a method similar to one used earlier (V. M. Agranovich and Yu. V. Konobeyev. FTT, 5, 2524, 1963). The interaction between charged particles of the crystal and the natural radiation field existing in the crystal is not assumed to be weak. The tensor of nonlinear effects is proportional to the corresponding anharmonicity coefficients. The general formula for the tensor of nonlinear polarizability

$$\epsilon_{ijl}(\vec{x}, \omega; \vec{x}', \omega'; \vec{x}'', \omega'') = \left(\frac{e^2}{4\pi}\right)^3 \frac{\Delta p(\vec{x}\omega) \Delta p_j(\vec{x}'\omega') \Delta p_l(\vec{x}''\omega'')}{\omega\omega'\omega''} T_{mn}^{(m,n,p,q)}$$

together with

$$T_{mn}(\vec{x}, \omega; \vec{x}', \omega'; \vec{x}'', \omega'') = [amn(-\vec{x}', \vec{x}; \omega + i\delta; -\omega' - i\delta) +$$

Card 1/2

L 44313-65

ACC NR: AT6015889

$$\begin{aligned}
 & + Q_{nlm}(-\vec{x}, \vec{x}; \omega' + i\delta, -\omega' - i\delta) + Q_{lmn}(\vec{x}, \vec{x}; -\omega - i\delta, \omega - i\delta) + \\
 & + Q_{lmm}(\vec{x}, \vec{x}; -\omega - i\delta, -\omega' - i\delta) + Q_{nlm}(-\vec{x}, -\vec{x}; \omega' + i\delta, \omega + i\delta) + \\
 & + Q_{mlm}(-\vec{x}', -\vec{x}; \omega' + i\delta, \omega + i\delta) / ,
 \end{aligned}$$

permits the tensor of nonlinear effects to be expressed in terms of $\Phi_{lmn}(\vec{x}, \omega; \vec{x}, \omega')$ and the tensor components $\mathcal{E}_{ij}(\omega, \vec{x})$. The case of limitingly weak exciton-phonon interaction is examined. The formula for the tensor for the exciton region of the spectrum takes the form

$$E_{ijl}(\vec{x}, \omega; \vec{x}, \omega'; \vec{x}, \omega') = \frac{4\pi i N}{V \omega \omega'} \sum_{\mu_1 \mu_2} \frac{(0/P_i/\vec{x}\mu_1)(\vec{x}\mu_1/P_j/\vec{x}\mu_2)(0/P_l/\vec{x}\mu_2)}{[\mathcal{E}_{\mu_1}(\vec{x}') - \hbar\omega][\mathcal{E}_{\mu_2}(\vec{x}) - \hbar\omega]} + \dots$$

The obtained equations are found to be more suitable than earlier ones in the vicinity of the exciton absorption bands as well as outside the absorption bands if the tensor E_{ijl} cannot be replaced by δ_{ij} . The authors thank V. L. Ginzburg and L. P. Pitayevskiy for discussion. Orig. art. has: 38 formulas.

AUTHORS: Toshinskiy, G. I., Kalashnikov, A. G.

TITLE: A method of calculating the absorber burnup in reactors

SOURCE: Teoriya i metody rascheta yadernykh reaktorov; sbornik statey. Ed. by G. I. Marchuk. Moscow, Gosatomizdat, 1962, 118-- 143

TEXT: The burnup of absorber material in reactors offers a possibility of compensating those effects that change reactivity. It has been studied only for particular cases (A. Radkovskiy, Lecture on Second Geneva Conference 1958; A. M. Smith and E. Jeffrey, Lecture on Second Geneva Conference 1958, Paper 86; The Physics of Intermediate Spectrum Reactors USAEC, 1958). Here it is given a more general treatment for intermediate thermal reactors. As the demand for minimum unbalance of reactivity contradicts the demand for minimum residual reactivity the optimum absorber characteristics will be the result of a compromise. These problems are subjected to detailed theoretical analysis. It is assumed that an absorber nucleus, after having absorbed one neutron, will have a zero cross section for subsequent absorptions. First the absorber burnup equations are

X

Card 1/2

B102/B186

A method of calculating the absorber...

studied when self-shielding is taken into account; then approximate expressions for the burnup law are examined. It is shown that the exact function $f(\beta)$ can be replaced by $1/(1+\gamma\beta)$ when γ is so chosen that the error of β in the range from 0 to β_{\max} is smallest; β is the optical thickness of the absorber. The approximation of β by a polynomial and the case of small betas are discussed. In what follows, the optimum conditions for heterogeneous arrangements and homogeneous fuel-absorber mixtures are investigated. Finally it is shown how the variation of the neutron spectrum that arises during the operation of the reactor affects the absorber burnup and how this effect can be taken into account in the case of a homogeneous reactor. There are 7 figures.
